## **CLAIMS**

## What is claimed is:

- 1 A method for processing incoming ISDN calls comprising:
  receiving at least two incoming calls;
  placing each of the incoming calls in a temporary call list;
  analyzing each of the incoming calls to determine video channel type; and
  moving each of the incoming calls to a permanent call list based on the video
  channel type of the call.
- 2. A method as recited in claim 1 wherein receiving at least two incoming calls occur within a time interval less than that required to process an incoming ISDN call.
- 3. A method as recited in claim 1 wherein analyzing each of the incoming calls uses a framing listening technique.
- 4. A method as recited in claim 3 wherein the framing listening technique distinguishes between H.221 framing, master bonding channel framing and slave bonding channel framing.
- 5. A method as recited in claim 1 further comprising transmitting a multi-frame pattern if the video channel type is slave bonding channel framing.
- 6. A method as recited in claim 7 further comprising determining whether a previously-sent video unit identifier has been returned.
- 7. A method as recited in claim 1 further comprising addressing as a new call an incoming call that is transmitting master bonding channel framing.
  - 8. A method as recited in claim 1 further comprising:
    grouping an incoming call with other channels comprising a video call; and

calculating a delay compensation.

9. A method as recited in claim 1 further comprising:

receiving a value representing a transfer flag;

receiving a value representing a channel identifier;

receiving a value representing at least one of a physical video unit identifier and a group identifier;

receiving a value representing a rate multiplier; and receiving a value representing a bonding mode.

10. A processor-based videoconferencing station comprising a medium storing instructions for causing the processor to:

receive at least two incoming ISDN calls;

place each of the incoming calls in a temporary call list;

analyze each of the incoming calls to determine video channel type; and

move each of the incoming calls to a permanent call list based on the video
channel type of the call.

- 11. The station of claim 10, wherein the instructions for analyzing each of the incoming calls use a framing listening technique.
- 12. The station of claim 11, wherein the framing listening technique distinguishes between H. 221 framing, master bonding channel framing and slave bonding channel framing.
- 13. The station of claim 10, the medium further storing instructions for causing the processor to:

transmit a multi-frame pattern if the video channel type is slave bonding channel framing.

14. The station of claim 13, the medium further storing instructions for causing the processor to:

determine whether a previously sent video unit identifier has been returned.

- 15. A videoconferencing station comprising:
  a receiver for at least two incoming ISDN calls;
  a temporary call list for incoming calls;
  an analyzer to determine video channel type of each of the incoming calls; and,
  a permanent call list for each video channel call type.
- 16. The station of claim 15, wherein the analyzer uses a framing listening technique.
- 17. The station of claim 16, wherein the framing listening technique distinguishes between H. 221 framing, master bonding channel framing and slave bonding channel framing.
- 18. The station of claim 15, wherein the analyzer further determines whether a previously sent video unit identifier has been returned.
